# Adapting Peer-to-Peer Topologies to Improve System Performance

Presented by Chi-Hung Chao

## Outline

- Introduction
- Topology Evolution Algorithm
- Balancing Bias Algorithm
- Experiment
- Analysis and Observation
- Conclusion and Discussion

### Introduction

- Improving the performance of unstructured Peer-to-Peer file sharing system.
- Controlling the routing protocol and network topology simultaneously.

### Introduction

• Flooding based search algorithms are very sensitive to the number of edges in the network graph.

- Edge Thinning
  - Reducing the total number of links
- Diameter Folding
  - Adding some useful links

#### • Edge Thinning

- Reducing search cost by removing the most redundant links without disconnecting the graph.
- Assigning a "score" to each link within the network to determine how useful it was across all searches.

#### • Edge Thinning

Edge Scoring for a Query Candidate Edges for Removal (Possible cumulative scores 0-6) Query + . +1 1st Gen Worst 2nd Gen Scoring 5 5 +13rd Gen Edges 4 0 + 0 = 0

#### • Edge Thinning

- Late message
  - Redundant messages received at a later time.
- Even-length cycles also result in simultaneous redundant message delivery, but no late message are passed.
- Some bandwidth is used without any benefit to search in these odd-length cycles.

#### • Edge Thinning

 This calculation-removal cycle can be repeated until the graph becomes disconnected, at which point the last edge removed can be re-inserted.

#### • Diameter Folding

 After having created a way to remove the most redundant links, we began considering how and when we might add useful links.

#### • Diameter Folding

- By breadth-first search protocol, the worst-case time for a search to reach all other nodes is the same as the graph diameter.
- One way to add shortcut links between all nodepairs whose minimum path length is the diameter.

#### • Diameter Folding

- So we perform the Diameter Folding algorithm, and then perform thinning from the folded topology.
- But an edge would often be added that was immediately removed by the next thinning step because the folding step was creating an odd cycle within the graph.

#### • Diameter Folding

- Ensuring that the new cycle that is being created is always of even length
  - Folding operation selects a pair of nodes at the diameter and connects them directly if the diameter is odd.
  - If the diameter is even, connects one of them to a neighbor along the path.

#### • Diameter Folding

Greatest Odd-Length Paths for Folding

Diameter

- – Odd Diameter Fold
- ..... Even Diameter Fold

### **Balancing Bias Algorithm**

- To balance nodes degrees
- In thinning
  - Remove the poor scoring links between nodes with high degrees.
- In Folding
  - Add links between distant nodes with low degree.

### **Experiments**

- Experiment 1
  - Fixed number of links.
- Experiment 2
  - Allowed the number of links to increase or decrease.

### **Experiment 1**

		Target	Actual	Initial Degree			Degree statistics after 5000 steps of alternating thin and fold					
Graph	Size	Mean	Mean	Statistics			Without		With			
		Degree	Degree				Balancing Bias			Balancing Bias		
Nodes	Links	_	_	Min	Max	Std	Min	Max	Std	Min	Max	Std
32	66	5	4.1	1	8	2.0	2	17	4.4	2	8	1.4
64	178	6	5.6	1	10	2.1	3	33	7.6	2	9	1.7
128	455	7	7.1	2	15	2.8	3	54	9.7	4	15	2.0
256	1020	8	8.0	1	17	2.9	4	59	10.5	4	17	2.7
512	2371	9	9.3	1	20	3.1	5	37	5.6	6	21	2.3
NOTE: Random graphs generated by probabilistically deciding whether to include												
each possible link, with the probability determined by target mean degree. Here,												
the target degrees mimic a base two hypercube of the same size.												

### **Experiment 2**

Initial Graph Topology		Degree	•	Path			Search		
initial Graph Topology	Min	Mean	Max	Min	Mean	Max	Min	Mean	Max

### **Conclusions and Discussions**

- These algorithm will lead to network performance improvements.
- But the algorithm need to be performed in a stable environment, and the bandwidth consumption of performing this algorithm maybe large.
